C++ Identifier Security using Unicode Standard Annex 39

C++ Identifier Security using Unicode Standard Annex 39

Date: 2022-01-17

Project: Programming Language C++

Audience: EWG

CWG WG14 WG21 SG-16

Reply-to: Reini Urban <reini.urban@gmail.com>

1 Abstract

In response to P1949R7

Adopt Unicode Annex 39 "Unicode Security Mechanisms" as part of C++ 23 (and C23).

- Comply to a variant of TR39#5.2 Mixed-Scripts Moderately Restrictive profile, but allow Greek scripts,
- Disallow all Limited Use TR31#Table_7 and Excluded scripts TR31#Table 4,
- Only allow TR39#Table 1 Recommended, Inclusion, Technical Identifier Type properties,
- Demand NFC normalization. Reject all composable sequences as ill-formed. (from P1949)
- Reject illegal combining mark sequences (Sk, Cf, Mn, Me) with mixed-scripts (SCX) as ill-formed. TR39#5.4

Optionally:

 Implementations may allow an optional #pragma unicode <LongScript> that Excluded scripts can be added to the allowed set of scripts per source file. Recommend binutils/linker ABI identifier rules: names are UTF-8, add add identifier checks. E.g. readelf -L -Ue.

In addition adopt this proposal as a Defect Report against C++20 and earlier. The author provides the libu8ident library (Apache 2 licensed) and its generated tables to all implementors.

2 Changes

none

3 Summary

P1949 correctly detected that Unicode identifiers are still not identifiable, and are prone to bidi- and homoglyph attacks. But it stated that implementing TR31 and TR39 would be too hard. Having properly implemented the Unicode Security Guidelines for identifiers for several years, plus pushed Rust to do so also, proves the contrary.

Further restriction of the TR31 profile to only recommended scripts leads to smaller sets for identifiers, and implementation of a proper TR39 mixed script profile and identifier types fixes most of the known unicode security problems with identifiers. The only remaining problems are bidi overrides in strings or comments, which cannot be handled with identifier restrictions, but tokenizer or preprocessor warnings, as recently added to gcc. #include filename restrictions should be done also, but that is out of the scope of this document, as the existing filesystems care much less about unicode security for identifiers than programming languages. Spoofing attacks on filenames are not yet seen in the wild, but will appear sooner or later, same as they appeared in browsers and email. Also names in C object files: linkers, .def files, ffi's.

Implementing TR39 mixed script detection per document (C++ Header and Source file) forbids insecure mixes of Greek with Cyrillic, dangerous Arabic RTL bidi attacks and most confusables. You can still write in your language, but then only in commonly written languages, and not mixed with others. Identifiers are still identifiable.

4 What will this proposal change

4.1 The set of TR31 XID characters will become much smaller

Restricting the **Identifier Type** plus the Recommended Scripts, plus demanding NFC will shrink the original XID set from 971267 codepoints to 93036 codepoints. The ranges expand from 36 to 315. (when split by scripts already, 25 splits happen).

 ID_Start consists of Lu + Ll + Lt + Lm + Lo + Nl, $+0ther_ID_Start$, $-Pattern_Syntax$, $-Pattern_White_Space$

131997 codepoints

 $ID_Continue\ consists\ of\ ID_Start,\ +\ Mn\ +\ Mc\ +\ Nd\ +\ Pc,\ +0ther\ ID\ Continue,\ -Pattern\ Syntax,\ -Pattern\ White\ Space.$

135072 codepoints (= ID Start + 3075)

XID_Start and XID_Continue ensure that isIdentifer(string) then isIdentifier(NFKx(string)) (removing the NFKC quirks)

XID_Start: 131974 codepoints, XID_Continue: 135053 codepoints
(= XID Start + 3098)

See 13 "Appendix A - C23XID_Start" and 13 "Appendix B - C23XID Continue"

4.2 Only Recommended scripts are now allowed, Excluded and Limited_Use not

These scripts will stay allowed:

Common Inherited Latin Arabic Armenian Bengali Bopomofo Cyrillic Devanagari Ethiopic Georgian Greek Gujarati Gurmukhi Hangul Han Hebrew Hiragana Katakana Kannada Khmer Lao Malayalam Myanmar Oriya Sinhala Tamil Telugu Thaana Thai Tibetan

These Excluded Scripts are initially disallowed TR31#Table_4 but can be optionally be allowed via a new #pragma unicode Script:

Ahom Anatolian_Hieroglyphs Avestan Bassa_Vah Bhaiksuki Brahmi Braille Buginese Buhid Carian Caucasian_Albanian Chorasmian Coptic Cuneiform Cypriot Cypro_Minoan Deseret Dives_Akuru Dogra Duployan Egyptian_Hieroglyphs Elbasan Elymaic Glagolitic Gothic Grantha Gunjala_Gondi Hanunoo Hatran Imperial_Aramaic Inscriptional_Pahlavi Inscriptional_Parthian Kaithi Kharoshthi Khitan_Small_Script Khojki Khudawadi Linear_A Linear_B Lycian Lydian Mahajani Makasar Manichaean Marchen Masaram_Gondi Medefaidrin Mende_Kikakui Meroitic_Cursive Meroitic_Hieroglyphs Modi Mongolian Mro Multani Nabataean Nandinagari Nushu Ogham

Old_Hungarian Old_Italic Old_North_Arabian Old_Permic Old_Persian Old_Sogdian Old_South_Arabian Old_Turkic Old_Uyghur Osmanya Pahawh_Hmong Palmyrene Pau_Cin_Hau Phags_Pa Phoenician Psalter_Pahlavi Rejang Runic Samaritan Sharada Shavian Siddham SignWriting Sogdian Sora_Sompeng Soyombo Tagalog Tagbanwa Takri Tangsa Tangut Tirhuta Toto Ugaritic Vithkuqi Warang_Citi Yezidi Zanabazar Square

These Limited Use Scripts are now disallowed TR31#Table_7

Adlam Balinese Bamum Batak Canadian_Aboriginal Chakma Cham Cherokee Hanifi_Rohingya Javanese Kayah_Li Lepcha Limbu Lisu Mandaic Meetei_Mayek Miao New_Tai_Lue Newa Nko Nyiakeng_Puachue_Hmong Ol_Chiki Osage Saurashtra Sundanese Syloti_Nagri Syriac Tai_Le Tai_Tham Tai Viet Tifinagh Vai Wancho Yi Unknown

The script property and its name are defined in TR24. We use the long Unicode Script property value, not the abbrevated 4-letter short name, which maps somehow to the 4-letter ISO 15924 Codes.

4.3 Documents with identifiers in many multiple scripts/languages will become illegal

C++23 (and C23) will follow the TR39 Security Profile 4 **Moderately Restrictive**, with an exception for Greek.

- · All identifiers in a document qualify as Single Script, or
- All identifiers in a document are covered by any of the following sets of scripts, according to the definition in Mixed Scripts:
 - Latin + Han + Hiragana + Katakana (Japanese)
 - Latin + Han + Bopomofo (Chinese)
 - Latin + Han + Hangul (Korean), or
- All identifiers in a document are covered by Latin and any one other Recommended script, except Cyrillic.

Thus it explicitly allows Greek together with Latin, because the only found unicode identifiers examples in the wild are Greek for math variable names, and Greek is forbidden in the TR39 Moderately Restrictive profile.

4.4 Mixed-script runs with combining marks will become illegal

C23++ will check for unlikely sequences of **combining marks**, and reject some. Combining Marks have no script property per se, but a variable list of allowed SCX scripts, which need to be checked against

the base character. Also 4 Japanese KATAKANA-HIRAGANA PRO-LONGED SOUND MARK modifier letters.

See 7.2 "SCX Extensions" and 7.3 "Combining marks script run detection for spoofing" below.

5 What will this proposal not change

5.1 The validity of "extended"" characters in identifiers

All current compilers allow characters outside the basic source character set directly in source today.

6 Why now

One driving factor for addressing this now is that GCC has fixed their long standing bug 67224 "UTF-8 support for identifier names in GCC". Clang has always supported too many code points in source code. MSVC in its usual configuration defaults to code page 1252, but can be told to accept UTF-8 source. With GCC now allowing it, the barrier to use of Unicode characters outside the basic source character set has dropped considerably. Use of characters via universal character names was always possible, but never widely used. Examples found in the wild of use of UCNs in identifiers come from compiler and related tool test suites, but it's trivial to come up with such spoofing attacks. There is no report yet from misuse in C ABI's from linkers and binutils.

Restricting the profile of characters is much easier if no one is depending on them.

The recent https://trojansource.codes effort caused gcc to emit a new bidi warning, and github to implement similar warnings. Note that secure identifiers don't help against bidi overrides in strings or comments, these issues are orthogonal.

There used to be no linter, but there is now one: **u8idlint** from https://github.com/rurban/libu8ident, which can be used to check for ALLOWED,SAFEC23,ID,XID,C11 or ALLUTF8 TR31 profiles, for various TR39 mixed script profile violations, confusables, invalid combining marks and TR15 normalization problems.

So far only Rust, cperl and Java follow a unicode security guideline for identifiers, zig and J refused to support non-ASCII identifiers. Everbody else is vulnerable to potential security attacks and does

allow non-identifiable identifiers. They should rename identifiers to "symbols".

7 TR24 Scripts, the SC and SCX properties

7.1 SC

C++ only needs to map unicode characters to a script property via a single byte. There are currently 161 scripts assigned, 32 of them are in common use as identifiers, hence called **Recommended** scripts. The rest is split up into 127-31 **Excluded** scripts, which are not in common use, and 161-127 **Limited_Use** scripts, which are not to be used in identifiers at all.

New scripts are added on a yearly basis, but nothing was added to the stable set of recommended scripts. For a while there was a list of **Aspirational** scripts to be added eventually, but this list was abandoned. Probably also because nobody but Java, cperl and Rust implemented its identifier profile by scripts, rather went with insecure identifiers.

For error messages and an optional pragma to allow certain Exluded scripts, we use the long **Script property value**. Do not use the term "script name", as this is ambigious and misused. The Script Property Value is the titlecased name of the script from the UCD, with spaces replaced by underscores. They are defined in the yearly updated Scripts.txt

7.2 SCX Extensions

Not all characters are uniquely used in a single script only. Many are used in a variable numbers of scripts. These are assigned to the Common or Inherited script, and are exactly specified in the ScriptExtensions.txt, aka SCX. The SCX property is a list of possible scripts per character. This list is using the short 4-letter script property, which needs to be resolved via the PropertyValueAliases.txt to its long script property value. (E.g. Syrc to Syriac)

Script_Extensions=Arab Syrc

064B..0655; Arab Syrc # Mn [11] ARABIC FATHATAN..ARABIC HAMZA BELOW

Script Extensions=Adlm Arab Mand Mani Ougr Phlp Rohg Sogd Syrc

0640 ; Adlm Arab Mand Mani Ougr Phlp Rohg Sogd Syrc # Lm ARABIC TATWEEL

Some of the SCX scripts contain only a single script. These could directly added to the list of SC scripts for the purpose of identifier security checks, but I advise against, for easier Combining Marks checks against the base character script. See below 7.3.

E.g.

3006 ; Hani # Lo IDEOGRAPHIC CLOSING MARK

U+3006 with the Common script property is assigned to the Hani -> Han script.

Multiple SCX list entries can resolved when the previous scripts in the identifier context are already resolved to one or the other possibility. Thus for SCX=(Arab Syrc) we need to check if Arabic or Syriac was already seen. If not, the new character with that SCX is illegal, violating our Mixed Script profile.

7.3 Combining marks script run detection for spoofing

Check for unlikely sequences of combining marks:

- Forbid sequences of the same nonspacing mark.
- Forbid sequences of more than 4 nonspacing marks (gc=Mn or gc=Me).
- Optionally forbid sequences of base character + nonspacing mark that look the same as or confusingly similar to the base character alone (because the nonspacing mark overlays a portion of the base character). An example is U+0069 LOWER-CASE LETTER I + U+0307 COMBINING DOT ABOVE.

Since we disallow already most combining marks (at least the Latin ones) with the requirement of NFC P1949R7, this set of cases is quite small.

Special-cases:

Using the Script property alone will not detect that the U+30FC (\square) KATAKANA-HIRAGANA PROLONGED SOUND MARK (Script=Common, SCX=Hira Kana, gc=Lm) should not be mixed with Latin. See TR39#5.4 and TR46. We only have to check only 4 such explicitly japanese-only PROLONGED SOUND MARKs, all other Lm modifiers may mix with all SCX.

The list of allowed combining mark characters (with Common or Inherited scripts) in the C23++ TR31 profile is: Lm Modifier_Letter, Mc Spacing_Mark, Mn Nonspacing_Mark, Me Enclosing_Mark. Sk and Cf are not part of XIDs.

67 matches for "XID_Continue # Lm" in buffer: DerivedCoreProperties.txt

```
02B0..02C1 ; XID_Continue # Lm [18] MODIFIER LETTER SMALL H..
```

MODIFIER LETTER REVERSED GLOTTAL STOP

02C6..02D1 ; XID_Continue # Lm [12] MODIFIER LETTER CIRCUMFLEX ACCENT..

MODIFIER LETTER HALF TRIANGULAR

. . .

513 matches for "XID_Continue # M" in buffer: DerivedCoreProperties.txt

```
0300..036F ; XID Continue # Mn [112] COMBINING GRAVE ACCENT..
```

COMBINING LATIN SMALL LETTER X

0483..0487 ; XID_Continue # Mn [5] COMBINING CYRILLIC TITLO..

COMBINING CYRILLIC POKRYTIE

. . .

From these 67 Lm plus 513 M[cn] ranges filtering out the non-C23 XID candidates, only #8 Identifier_Type = Recommended, Inclusion, Technical, plus only #4.2 Recommended Scripts, plus only codepoints with multiple SCX entries, plus only codepoints which don't decompose to NFC, leads only to the Lm characters, which can mix with all scripts. Not a single Mn or Mc codepoints is left.

So some of the Common XID_Continue marks therefore cannot be detected with the SCX logic. But all of them do not combine with Latin and are already filtered by the C23 Mixed Script profile. And all of the Combining Marks are caught by the NFC requirement.

Most Lm Modifier Letters (besides the 4 Japanese PROLONGED SOUND MARKs) are freestanding base characters, which can be combined with any other letter.

See TR31#2.1 Combining Marks and TR31#2.2 Modifier Letters

See also TR24#5.1 Handling Characters with the Common Script Property and TR24#5.2 Handling Combining Marks.

8 TR39 Identifier Type

The **Identifier Type** property TR39#Table 1 recommendation should be mandatory, with the addition of the Technical Identifier Type to be allowed.

I.e. Limited_Use, Obsolete, Exclusion, Not_XID, Not_NFKC, Default_Ignorable, Deprecated, Not_Character are not part of identifiers. Allowed are Recommended, Inclusion, Technical TR39 Identifier Types.

There are 80 Technical ranges added to the original list of Recommended and Inclusion ID's.

grep ', U8ID_Technical' scripts.h | egrep -v 'Not_XID|U8ID_Obsolete|U8ID_Exclusion'
See 17 Appendix E - IDType Technical.

9 TR39 Mixed Scripts

TR39 defines some security profiles for identifiers to avoid the most common identifier insecurities, that identifiers will stay identifiable.

We choose a variant of the **Moderately Restrictive** profile, with an exception for Greek. I called this profile C23_4 or SAFEC23 in libu8ident.

- All identifiers in a document qualify as Single Script, or
- All identifiers in a document are covered by any of the following sets of scripts, according to the definition in Mixed Scripts:
 - Latin + Han + Hiragana + Katakana (Japanese)
 - Latin + Han + Bopomofo (Chinese)
 - Latin + Han + Hangul (Korean), or
- All identifiers in a document are covered by Latin and any one other Recommended script, except Cyrillic.

Thus it prevents Cyrillic mixed with Latin or any other script, but does allow any East-Asian CFK language, other common and widely used languages and Latin mixed with Greek, mainly used for its mathematical symbols. Many mathematical symbols already exists outside of Greek, but these are mainly used for operators in advanced programming languages, not as identifiers. See also http://xahlee.info/comp/unicode math operators.html for a nice overview.

E.g. here we have some:

- U+2217 (*) ASTERISK OPERATOR (Script=Common). Not XID
- U+2107 ([]) EULER CONSTANT (Script=Common, Lu) is a proper letter, but with Restricted IdentifierStatus.
- U+2126 (Ω) OHM SIGN (Script=Greek, L&) is a greek letter, but with Restricted IdentifierStatus.
- U+2127 (*\overline{O}) INVERTED OHM SIGN (Script=Common, So). Obsolete, Not XID

TR39 also compiles a convenient IdentifierStatus list. But all the math letters with Script=Common from U+2100 to U+2200 are re-

stricted, as Greek is forbidden mixed with Latin in the original TR39 Moderately Restrictive profile. These are allowed according to the TR31 and TR39 rules of SAFEC23, so we need to come up with our own list of XID_Start/XID_Continue codepoints, excluding the Limited Use and Excluded scripts. And if an implementation choses to allow Excluded scripts with more logic to allow only this script.

It is recommended to already exclude Limited Use and Excluded scripts from the initial list of identifier ranges, as this is the most common use-case, and shortens the common search paths. Only with the #pragma Unicode ExcludedScript search the full XID lists and the full scripts list.

The TR39 Mixed Scripts profile alone does not prevent from all spoofing attacks, but the additional rules from 7.3 "Combining marks script run detection for spoofing" are kept tiny.

10 Contexts

This is not discussed in any of the unicode security guidelines for identifiers. One could argue that a mixed-script profile is valid only for a single identifier, or it is valid for whole source file document.

If valid for only a single identifier you could arbitralily mix up Cyrillic with Greek identifiers in a C++ namespace, and thus these identifiers would not be identifiable anymore, as both both can render to the very same glyphs. Thus we adopt the notion of identifier contexts.

With programming languages this is a source file, with objects files this is a module. For identifiers in object files see below 12 Issues with binutils, linkers, exported identifiers. For filesystems this would be a directory.

For every source file we need to store a context with the list of already seen scripts and how many. The maximal number of scripts is 4, for the case of Japanese mixed with Latin. (Katakana + Hiragana + Han + Latin), thus we can save that list in a single 4-byte word, and the lookup and memory management is trivial.

11 Implementations and Strategies

I implemented for cperl, a fork of perl5, the General Security profile "Moderately restrictive" (4) for identifiers in 2017, together with transparent normalization of NFC. This is a dynamic language with the need for fast tokenizing, and compilation. Still I did not see a

need to restrict all source code identifiers to be already in NFC. Even with the added unicode checks and dynamic normalization the tokenizer is still faster than the simplier perl5 tokenizer.

Then when GCC went to full insecure identifiers I implemented the more general libu8ident library, which can be used with all known TR39 identifier type profiles, the mixed-script security profiles, TR31 XID character sets and all TR15 normalizations. There I tested various performance strategies of the unicode lookups. Tested was CRoaring, which was only useful for sets of single codepoints, the list of confusables. Most of the needed lists were best structured as binary-search in range pairs. Most of them were fastest with special-casing the codepoints below U+128 with a simple linear search. Binary search in an Eytzinger layout was not convincibly faster, neither hybrid searches by 1. splitting up ranges from single codepoints, nor 2. seperating 16bit from 32bit codepoints.

12 Issues with binutils, linkers, exported identifiers

The crux with C and somewhat also C++ identifiers, is that they can be used with other earlier compilers or languages without any unicode security profile or restriction. ffi's are very common, libraries or .def files even more, thanksfully unicode names not at all yet.

binutils and linkers treat names as zero-terminated binary garbage, same as in most current filesystems. Identifiers are not identifiable there, and names are charset (=user) specific, whilst there are no header fields for the used charset (e.g. if SHIFT-JIS or UTF-8), nor are there any rules for name lookup (normalization). This is not solvable here (in C nor C++), only there. Only in the Rust ecosystem there are proper unicode identifier rules, but Rust can link against C++/C. I haven't detected any exported unicode names in the wild, they are only used in local symbols still. UTF-16 compilers such as MSVC do export their UNICODE names either in the local character set or as UTF-8. If used wildly, object files would not link anymore, as local character sets vary, and there is no character set standard defined.

The C++/C working groups should urge the binutils/linker working groups to adopt a more precise specification how exported identifiers are represented in object files and libraries: UTF-8 or any charset, and how they are looked up: any normalization, NFC or not at all. My recommendation would be to interpret them as UTF-8, require NFC, and reject all illegal UTF-8 and non-NFC identifiers. As long as there no unicode names in the wild this is still easy. There are

also many object file producers in the wild, with possibly completely insecure unicode names in the future.

binutils readelf -L -Ul is currently broken displaying unicode identifiers. I have patches to display them in the current multi-byte locale, and to add u8ident checks with -L. I haven't found any violations so far in my used libraries.

Even better would be for the C ABI's to also adopt secure unicode identifiers, as linkers and FFI's have the same unicode security problems as compilers, interpreters and filesystems. Otherwise they should at least clarify that their names/"symbols" are not identifiable, and implementation defined and their interpretation locale specific. (i.e. you cannot copy them across locales).

13 Appendix A - C23XID_Start

Created with mkc23 from libu8ident. The SCX is modelled as if your compiler would allow static initialization of strings as {char,...,0}.

```
struct sc c23 {
    uint32 t from;
    uint32 t to;
    enum u8id_sc sc; // Scripts
    enum u8id_gc gc; // General Category. GC L is L& (all letters)
                      // GC V is varying
    const char *scx; // List of ScriptExtensions, maxsize 8 for U+1CF2
};
// Filtering allowed scripts, XID Start, safe IDTypes, NFC and !MARK
// Ranges split at GC and SCX changes
const struct sc c23 safec23 start list[431] = {
    {'$', '$', SC_Latin, GC_Sc, NULL},
    {'A', 'Z', SC_Latin, GC_Lu, NULL},
